ABSTRACT

To account for head misplacement while servowriting, conditional writing and/or

trimming of servo information can be used. Conditional servowriting allows servowriting to be disabled

when it is determined that servo information will not be written and/or trimmed at a desired location

or within a threshold distance of a desired location. For example, if a distance between a write

element or a predicted location of servo information and a desired location of the servo information

or write element exceeds a threshold, writing and/or trimming can be inhibited. Servowriting can be

resumed when it is determined that servo information will be written or trimmed at a desired location

or within a threshold distance of a desired location. A servowriting step or pass is not re-started when

the threshold is exceeded and those wedges for which servo information was not writtten and/or

trimmed can be attempted during subsequent revolutions of the rotatable storage medium.
